1 General Description of Aluminum Electrolytic Capacitors

1-1 The Principle of Capacitor

The principle of capacitor can be presented by the principle drawing as in Fig.1-1.

When a voltage is applied between the metal electrodes placed opposite on both surfaces of a dielectric, electric charge can be stored proportional to the voltage.

\[ Q = C \cdot V \]

- \( Q \): Quantity of electricity (C)
- \( V \): Voltage (V)
- \( C \): Capacitance (F)

C, called the capacitance of capacitor, is expressed by the following expression with the electrode area \( S \) [m²], the electrode spacing \( t \) [m] and the dielectric constant of dielectric \( \varepsilon \cdot \varepsilon_0 \):

\[ C = \varepsilon_0 \cdot \varepsilon \cdot \frac{S}{t} \]

\( \varepsilon_0 \): Dielectric constant in vacuum \((=8.85 \times 10^{-12} \text{ F/m})\)

The dielectric constant of an aluminum oxide film is 7 to 8. Larger capacitances can be obtained by enlarging the electrode area \( S \) or reducing \( t \).

Table 1-1 shows the dielectric constants of typical dielectrics used in the capacitor. In many cases, capacitor names are determined by the dielectric material used, for example, aluminum electrolytic capacitor, tantalum capacitor, etc.

</tbody>
</table>

Although the aluminum electrolytic capacitor is small, it has a large capacitance. It is because the electrode area is roughened by electrochemical etching, enlarging the electrode area and also because the dielectric is very thin.

The schematic cross section of the aluminum electrolytic capacitor is as in Fig.1-2.

1-2 Equivalent Circuit of the Capacitor

The electrical equivalent circuit of the aluminum electrolytic capacitor is as presented in the following figure.

- \( R_1 \): Resistance of terminal and electrode
- \( R_2 \): Resistances of anodic oxide film and electrolyte
- \( R_3 \): Insulation resistance because of defective anodic oxide film
- \( D_1 \): Oxide semiconductor of anode foil
- \( C_1 \): Capacity of anode foil
- \( C_2 \): Capacity of cathode foil
- \( L \): Inductance caused by terminals, electrodes, etc.

2 About the Life of an Aluminum Electrolytic Capacitor

2-1 Estimation of life with minimal ripple current (negligible).

Generally, the life of an aluminum electrolytic capacitor is closely related with its ambient temperature and the life will be approximately the same as the one obtained by Arrhenius’ equation.

\[ L = L_0 \times 2^\left(\frac{T_0-T}{10}\right) \]

Where \( L_0 \): Life at temperature \( T \)
\( L_0 \): Life at temperature \( T_0 \)

The effects to the life by derating of the applied voltage etc. are neglected because they are small compared to that by the temperature.
2-2 Estimation of life considering the ripple current.
The ripple current affects the life of a capacitor because the internal loss (ESR) generates heat. The generated heat will be:

\[ P = I^2R \] (2)

Where \( I \) : Ripple current (Arms)
\( R \) : ESR (\( \Omega \))

With increase in the temperature of the capacitor:
\[ \Delta T = \frac{T^2 \times R}{A \times H} \] (3)

Where \( \Delta T \) : Temperature increase in the capacitor core (deg.)
\( I \) : Ripple current (Arms)
\( R \) : ESR (\( \Omega \))
\( A \) : Surface area of the capacitor (cm\(^2\))
\( H \) : Radiation coefficient (Approx. 1.5 to 2.0 \( \times 10^{-5} \text{W/cm}^2\text{C} \))

The above equation (3) shows that the temperature of a capacitor increases inversely proportional to the square of the applied ripple current and ESR, and in inverse proportion to the surface area. Therefore, the amount of the ripple current determines the heat generation, which affects the life. The value of \( \Delta T \) varies depending on the capacitor types and operating conditions. The usage is generally desirable if \( \Delta T \) remains less than 5°C. The measuring point for temperature increase due to ripple current is shown below:

![Measuring point](image)

Test results:
(1) The life equation considering the ambient temperature and the ripple current will be:

\[ L = Ld \times 2 \left( \frac{T_0 - T}{10} \right) \times K \left( \frac{-\Delta T}{10} \right) \] (4)

Where \( Ld \) : Life at DC operation (h)
\( K \) : Ripple acceleration factor
\( K=2 \), within allowable ripple current
\( K=4 \), if exceeding allowable ripple current
\( T_0 \) : Upper category temperature (°C)
\( T \) : Operating temperature (°C)
\( \Delta T \) : Temperature increase at capacitor core (deg.)

(2) The life equation based on the life with the rated ripple current applied under the maximum guaranteed temperature will be a conversion of the above equation (4), as below:

\[ L = Lr \times 2 \left( \frac{T_0 - T}{10} \right) \times K \left( \frac{-\Delta T}{10} \right) \] (5)

Where \( Lr \) : Life at the upper category temperature with the rated ripple current (h)
\( \Delta T \) : Temperature increase at capacitor core, at the upper category temperature (deg.)

Since it is actually difficult to measure the temperature increase at the capacitor core, the following table is provided for conversion from the surface temperature increase to the core temperature increase.

<table>
<thead>
<tr>
<th>Case diameter</th>
<th>~10</th>
<th>12~16</th>
<th>18</th>
<th>22</th>
<th>25</th>
<th>30</th>
<th>35</th>
</tr>
</thead>
<tbody>
<tr>
<td>Core / Surface</td>
<td>1.1</td>
<td>1.2</td>
<td>1.25</td>
<td>1.3</td>
<td>1.4</td>
<td>1.6</td>
<td>1.65</td>
</tr>
</tbody>
</table>

The life expectancy formula shall in principle be applied to the temperature range between the ambient temperature of \(+40°C\) and upper category temperature. The expected life time shall be about fifteen years at maximum as a guide in terms of deterioration of the sealant.

![Fig. 2-1 Life Expectancy Chart](image)
2-3 Practical Examples of Life Expectancy

As practical examples of life expectancy, we introduce 250V 560 μF in the LAT Series considering the effect of high-frequency component. Figures 2-2 to 2-4 show the simulated ripple current waveforms when the high-frequency component for switching is superimposed on the commercial frequency component.

![Fig.2-2 Ripple Current Waveform of Capacitor](image)

![Fig.2-3 Low-frequency component](image)

![Fig.2-4 High-frequency component](image)

Each of the above may be obtained as the effective ripple current value. Assuming that the ripple current waveform of the low-frequency component is generally approximated to the full-wave rectification waveform as shown in Fig.2-3, we obtain the effective ripple current value \( I_L \) as follows:

\[
I_L = \frac{I_{PL}}{\sqrt{2}} = 0.707 \times I_{PL}
\]

Since the ripple current waveform of the high-frequency component is approximated to the rectangular as shown in Fig.2-4, the effective current value of high-frequency component \( I_H \) is given by

\[
I_H = \sqrt{\frac{1}{T} \int_{t_1}^{t_2} I_{PH}^2 dt_1} = I_{PH} \sqrt{\frac{t_2 - t_1}{T}}
\]

The reason why the ripple current affects the life is due to the heat generated by the ESR (R) of capacitor. That is, \( \Delta T \) by heat generation can be expressed by

\[
\Delta T \propto I^2 \times R
\]

Therefore, when ripple currents with different frequencies are handled, each current value must first be squared and then summed. That is:

\[
I = \sqrt{(I_L)^2 + (I_H)^2}
\]

Now, we proceed to specific examples assuming that the effective ripple current values of low-and high-frequencies have been obtained by the above methods.

Data A (Test piece and basic data)

<table>

</tr>
</tbody>
</table>

To verify the effect of the high-frequency component, the expected life will be calculated for each of three high-frequency ripple current conditions.

![Fig.2-5 Frequency Characteristics of ESR](image)

Figure 2-5 shows a typical example of frequency characteristics of ESR, indicating that the ESR decreases with increasing frequencies. Therefore, the high-frequency component has less effect on the heat generation of capacitor than low-frequency component. Next, we calculate the expected life according to each condition to compare with the case with no high-frequency component.

For Data B, the currents are converted to 120Hz by the frequency conversion factor for the cases of ignorance of the high-frequency component, and each high-frequency component condition.

\[
I = \frac{I_1}{1} = 2.4A
\]

\[
I_1 = \sqrt{(2.4)^2 + (0.36/1.18)^2} \approx 2.42A
\]

\[
I_2 = \sqrt{(2.4)^2 + (0.72/1.18)^2} \approx 2.48A
\]

\[
I_3 = \sqrt{(2.4)^2 + (1.2/1.18)^2} \approx 2.61A
\]

Explained here is about the frequency conversion factor. As described above, the heat generation (or temperature rise = \( \Delta T \)) affecting the life is proportional to the ESR of capacitor. In addition, the fundamental frequency is 120Hz in measurement of capacitor characteristics, and the ripple current is also specified with this frequency; it is thus more convenient to calculate by converting the current value to that with the same temperature rise at 120Hz.

The ESR of aluminum electrolytic capacitor is frequency dependent.
3 To calculate Balance when connecting in series

3-1 Circuit layout
Circuit for connecting two capacitors (C1, C2) in series and equivalent circuit can be illustrated as below figure. Formula to calculate a balance resistance \( R_b \) of below figure is shown as follows.

Following are the preconditions of the circuit.

1. \( V_0 \) shall be the rated voltage (\( =V_0 \)). \( (V_1<V_2) \)
2. \( V \) shall be a times \( V_0 \times 2. V = 2aV_0 \) \( (a<1) \)
3. \( R_b \) shall equal \( R_1 \times b \). \( (b<1) \) \( (1) \)

3-2 Formulas to calculate \( [R_b] \)

3-2-1 Following formula can be established from balanced condition.

\[
V_i \left[ \frac{1}{R_1} + \frac{1}{R_b} \right] = V_2 \left[ \frac{1}{R_b} \right]
\]

\( (2) \)

3-2-2 Following formula can be established from preconditions.

\[
V_i = V - V_2
\]

\( (3) \)

\[
V_i = 2aV_0 - V_2
\]

\( (4') \)

3-2-3 Put formulas \( (1), (3) \) and \( (4') \) in formula \( (2) \).

\[
(2aV_0 - V_2) \left[ \frac{R_1}{R_1} + \frac{R_b}{R_b} \right] = V_2 \left[ \frac{bR_1}{bR_1} + \frac{R_b}{R_b} \right]
\]

\[2abV_0(R_1 + R_b) = V_2 \{b(R_1 + R_b) + bR_1 + R_b\}
\]

\[2ab(R_1 + R_b) \leq 2br_1 + (1+b)R_b\]

Accordingly, balance resistance \( R \) shall be the following formula.

\[
R_b \leq 2br_1 \frac{(1-a)}{(2a-1) \times b-1}
\]

\( (5) \)

3-3 Calculation Example
Calculate the value of the balance resistance in the case of connecting two 400V 470µF (LC standard value : 1.88mA) capacitors in series.

\[
R_i = \frac{400(V)}{1.88(mA)} = 213(k \Omega)
\]

If \( a=0.8 \), \( 400(V) \times 2 \times 0.8 = 640(V) \) as an impressed voltage.
If \( b=2 \), \( R_2 = bR_1 = 426(k \Omega) \), LC=0.94(mA).
Balance resistance \( R_b \) will be.

\[
R_b \leq 2 \times 2 \times 213(k \Omega) \frac{(1-0.8)}{(2 \times 0.8) \times 2-1} = 852(k \Omega)
\]

4 Regarding Recovery Voltage
- After charging and then discharging the aluminum electrolytic capacitor, and further causing short-circuit to the terminals and leave them alone, the voltage between the two terminals will rise again after some interval. Voltage caused in such case is called recovery voltage. Following is the process that causes this phenomenon :
  - When the voltage is impressed on a dielectric, electrical transformation will be caused inside the dielectric due to dielectric action, and electrification will occur in positive-negative opposite to the voltage impressed on the surface of the dielectric. This phenomenon is called polarization action.
  - After the voltage is impressed with this polarization action, and if the terminals are discharged till the terminal voltage reaches 0 and are left open for a while, an electric potential will arise between the two terminals and thus causes recovery voltage.
  - Recovery voltage comes to a peak around 10 to 20 days after the two terminals are left open, and then gradually declines. Recovery voltage has a tendency to become bigger as the component (stand-alone base type) becomes bigger.
  - If the two terminals are short-circuited after the recovery voltage is generated, a spark may scare the workers working in the assembly line, and may put low-voltage driven components (CPU, memory, etc.) in danger of being destroyed. Measures to prevent this is to discharge the accumulated electric charge with resistor of about 100 to 1k\( \Omega \) before using, or ship out by making the terminals in short-circuit condition by covering them with an aluminum foil at the production stage. Please consult us for adequate procedures.
5 Electrode Foil Development Technology

5-1 Corrosion inhibition of cathode foil
Inactive treatment is implemented to ensure long life by inhibiting natural corrosion of the cathode foil. Fig. 3-1 shows its effects with values of the polarization resistance inversely proportional to the corrosion rate using the AC impedance method (FRA). This indicates that the cathode foil used in the High reliability capacitors has the polarization resistance higher than that of the conventional capacitors owing to corrosion inhibition.

5-2 Sealing material permeability of electrolyte
To ensure long life, a low permeable lactone solvent for the sealing material is used as the main solvent of the electrolyte of the High reliability capacitor. Fig. 3-2 shows the test results on the permeability obtained by changing the weight of the capacitors produced with different types of electrolytes at a high temperature.

5-3 Airtightness of sealing material
Since the electrolyte is stable for hours, the key element for capacitor’s life is the sealing material. By optimizing the crosslinking density of the sealing material polymer, the sealing material of the High reliability capacitor attains its long life with electrolyte permeability less than that of the conventional capacitors. Fig. 3-3 shows the test results on the airtightness of the sealing material obtained by changing the weight of the capacitors at a high temperature, producing capacitors with the conventional sealing material and improved one both containing the electrolyte used in the High reliability capacitor.

5-4 Long-time stability of electrolyte
The electrolyte used in the High reliability capacitor is stable with low initial resistivity and small secular changes at a high temperature. Fig. 3-4 shows change in resistivity at 105°C.

5-5 Dielectric formation voltage and leakage current characteristics of anode foil
To increase the operating life by controlling the gas generation inside capacitor because of 1.5 to 2 times the rated voltage, while that of the previous capacitor is about 1.3 times the rated voltage.

5-6 Lowered ESR of Electrode Foil
To reduce the ESR of electrolytic capacitor, we have improved our chemical conversion technology for anode foil to develop lower ESR electrode foil compared to the conventional product as shown in Fig. 3-6.
